

# Test Definition: 6MAMM

6-Monoacetylmorphine (6-MAM),  
Confirmation, Meconium

## Overview

### Useful For

Detection of in utero heroin exposure up to 5 months before birth

### Special Instructions

- [Clinical Toxicology CPT Code Client Guidance](#)

### Method Name

Liquid Chromatography Tandem Mass Spectrometry (LC-MS/MS)

### NY State Available

Yes

## Specimen

### Specimen Type

Meconium

### Ordering Guidance

For chain-of-custody testing, order MAMMX / 6-Monoacetylmorphine (6-MAM) Confirmation, Chain of Custody, Meconium.

### Specimen Required

**Supplies:** Stool container, Small (Random), 4 oz (T288)

**Container/Tube:** Stool container

**Specimen Volume:** 1 g (approximately 1 teaspoon)

#### Collection Instructions:

1. Collect entire random meconium (newborn's first bowel movements) specimen.
2. Send specimen frozen.

**Additional Information:** When refrigerated, a significant percentage of 6-monoacetylmorphine (MAM) will convert to morphine in less than 24 hours.

### Forms

If not ordering electronically, complete, print, and send a [Therapeutics Test Request](#) (T831) with the specimen.

### Specimen Minimum Volume

0.3 g (approximately 1/4 teaspoon)

### Reject Due To

Grossly bloody	Reject; Pink OK
Stool; diapers	Reject

## Specimen Stability Information

Specimen Type	Temperature	Time	Special Container
Meconium	Frozen	14 days	

## Clinical & Interpretive

### Clinical Information

Heroin (diacetylmorphine) is a semisynthetic opiate that is closely related to morphine. It is no longer used clinically in the United States, though it is used elsewhere for rapid relief of pain.<sup>(1)</sup> Like morphine and other opiates, its relaxing and euphoric qualities make heroin a popular drug of abuse. Heroin is commonly injected intravenously, although it can be administered by other means such as snorting, smoking, or inhaling vapors.

Heroin shares the core structure of morphine with the addition of 2 acetyl groups, which are thought to enhance its permeation into the central nervous system.<sup>(2,3)</sup> Heroin is metabolized by sequential removal of these acetyl groups; loss of the first acetyl converts heroin into 6-monoacetylmorphine (6-MAM).<sup>(2,3)</sup> Heroin is rarely found in meconium since only 0.1% of a dose is excreted unchanged. 6-MAM is a unique metabolite of heroin, and its presence is a definitive indication of heroin use. Like heroin, 6-MAM has a very short half-life; however, its detection time in meconium, the first fecal material passed by the neonate, is uncharacterized. 6-MAM is further metabolized into morphine, the dominant metabolite of heroin, and morphine will typically be found in a specimen containing 6-MAM.

Opiates, including heroin, have been shown to readily cross the placenta and distribute widely into many fetal tissues.<sup>(4)</sup> Opiate use by the mother during pregnancy increases the risk of prematurity and being small for gestational age. Furthermore, infants who have been exposed to heroin exhibit an early onset of withdrawal symptoms compared with infants who have been exposed to methadone. Infants exposed to heroin demonstrate a variety of symptoms including irritability, hypertonia, wakefulness, diarrhea, yawning, sneezing, increased hiccups, excessive sucking, and seizures. Long-term intrauterine drug exposure may lead to abnormal neurocognitive and behavioral development as well as an increased risk of sudden infant death syndrome.<sup>(5)</sup>

The disposition of drug in meconium is not well understood. The proposed mechanism is that the fetus excretes the drug into bile and amniotic fluid. The drug accumulates in meconium either by direct deposit from bile or through swallowing of amniotic fluid.<sup>(6)</sup> The first evidence of meconium in the fetal intestine appears at approximately the 10th to 12th week of gestation, and it slowly moves into the colon by the 16th week of gestation.<sup>(7)</sup> Therefore, the presence of drugs in meconium has been proposed to be indicative of in utero drug exposure during the final 4 to 5 months of pregnancy, a longer historical measure than is possible by urinalysis.<sup>(6)</sup>

### Reference Values

Negative

Positive results are reported with a quantitative liquid chromatography tandem mass spectrometry result.

Cutoff concentration: 5 ng/g

**Interpretation**

The presence of 6-monoacetylmorphine (6-MAM) in meconium is definitive for heroin use by the mother. However, the absence of 6-MAM does not rule-out heroin use because of its short half-life and stability.

**Cautions**

The short half-life and stability of 6-monoacetylmorphine (6-MAM) may prevent its detection in heroin users.

6-MAM is metabolized to morphine, but the presence of morphine alone is not sufficient evidence to prove heroin use. 6-MAM is the only definitive metabolite of heroin.

**Performance****Method Description**

Meconium is mixed with internal standard and extracted with methanol. The methanolic extract is further processed by solid-phase extraction. The extract is analyzed by liquid chromatography tandem mass spectroscopy.(Unpublished Mayo method)

**PDF Report**

No

**Day(s) Performed**

Monday through Sunday

**Report Available**

2 days

## Specimen Retention Time

2 weeks

## Performing Laboratory Location

Mayo Clinic Laboratories - Rochester Superior Drive

## Fees & Codes

### Fees

- Authorized users can sign in to [Test Prices](#) for detailed fee information.
- Clients without access to Test Prices can contact [Customer Service](#) 24 hours a day, seven days a week.
- Prospective clients should contact their account representative. For assistance, contact [Customer Service](#).

### Test Classification

This test was developed and its performance characteristics determined by Mayo Clinic in a manner consistent with CLIA requirements. It has not been cleared or approved by the US Food and Drug Administration.

### CPT Code Information
